

This document describes step by step what the `cloud-detection.py` does.

The first draft will only conclude detection of Azure, however, implementing other cloud providers should be added easily.

- Resolve the IP
- Check the nameservers
- Check the MX, TXT, ... records
- Check the certificates
- Check the `server` attribute in the Response Header
- Check the Autonomous System
- Crawl for URLs (and check if they are Azure/AWS, ...)
- builtwith API (if allowed?)
